ASSOCIATION

## DISCLAIMER

NCMA promotes the use of concrete masonry through the development and dissemination of technical information. This manual was compiled to assist the designer, builder, or owner in the preparation of constructing with concrete masonry. The discussion, design tables, and design philosophies are intended to assist architects and engineers in the design of concrete masonry and precast concrete lintels and to acquaint builders and contractors with recommended construction methods and details.

The material presented does not cover all possible situations but is intended to represent some of the more widely used concrete masonry design and construction details and other pertinent information. Factors such as construction practices and building code requirements can vary significantly, even in the same locality. For this reason, the information contained in the handbook is necessarily of a general nature when illustrating typical design conditions, assumptions, and procedures. The actual design of lintels, preparation of working drawings, and similar services are best accomplished by a qualified architect or engineer familiar with local conditions and code requirements.

Care has been taken to ensure that the information included in this manual is as accurate as possible. However, NCMA does not assume responsibility for errors or omissions resulting from the use of this manual or in its use when preparing plans or specifications.

## INTRODUCTION

Openings in concrete masonry walls are typically spanned by horizontal structural members known as lintels. Depending upon regional nomenclature, the terms lintel and beam are often interchanged. Regardless of the terminology used, the design approach and philosophy are identical for both elements. The purpose of these members is to support the weight of the wall above the opening, as well as any additional imposed loads. Lintels can be constructed from a variety of materials. The focus of this manual is on reinforced concrete masonry lintels and precast reinforced concrete lintels. Reinforced concrete masonry lintels may have an advantage in that the bond pattern and surface texture of the surrounding masonry is not interrupted.

Primarily designed as simply supported beams, lintels are sometimes constructed as a portion of a continuous bond beam course. This type of installation offers several distinct advantages, especially when the lintel is part of the top course of masonry walls.

All reinforced concrete masonry structural members can be designed by one of two methodsallowable stress design and strength design-in accordance with the 2002 Building Code Requirements for Masonry Structures (ACI 530/ASCE 5/ TMS 402) [1], henceforth referred to as the MSJC Code (for the Masonry Standards Joint Committee which oversees its development). Its companion document, Specification for Masonry Structures (ACI 503.1/ASCE 6/TMS 602) [2], referred to as
the MSJC Specification, covers the material and construction requirements for masonry.

In accordance with the allowable stress design provisions of the MSJC Code, structural elements are proportioned such that the stresses resulting from applied service loads do not exceed code prescribed maximum allowable stresses, which are some fraction of the strength level stress of the element. In contrast, when using the strength design method of the MSJC Code, the anticipated service loads are scaled up or down based upon the variability and predictability of the load under consideration. Simultaneously, the nominal strength of the element (the strength at which failure is initiated) is reduced by an appropriate strength reduction factor to account for design issues such as material variability.

Design of precast concrete lintels is governed by the 1999 Building Code Requirements for Structural Concrete (ACI 318) [3]. ACI 318 uses the strength design method in the design of precast concrete lintels.

The remainder of this design guide is divided into five sections. First, a discussion on the materials commonly used for lintel construction is presented. Next, a detailed discussion on design loads presents lintel loading conditions and discusses arching action of masonry walls. The aspects and parameters of lintel design are presented followed by design examples. Finally, lintel design tables are presented.

## Section 2

## MATERIALS

Materials used for reinforced precast and masonry lintels include cement, aggregates, concrete masonry units, mortar, grout, and steel reinforcement. These materials must meet the applicable specifications published by ASTM International. Applicable specifications for these materials are listed in Table 2.1.

Units. Concrete masonry units suitable for lintel construction come in a variety of shapes and sizes. Some typical shapes are shown in Figure 2-1. Lintel units are often U-shaped and available in various depths.

Solid bottom units confine the grout in the lintel. Attention should be given to the bottom thickness and the shape of the lintel as they may limit the number of reinforcing bars that can be placed effectively. Where open bottom bond beam units are used to construct lintels, the bottom is blocked to confine the grout. Lintel units are specified to comply with ASTM C 90.

Mortar. Mortar is required to comply with ASTM C 270 and is governed by either of two specifications: (1) the proportion specification, which pre-

Table 2.1: Standard Material Specifications

C. For finished masonry openings, or metal and wood sash.

Knock Out Bond Beam
Figure 2-1: Lintel and Bond Beam Units
scribes the parts by volume of each constituent material required to provide a specific mortar type, or (2) the property specification, which allows approved materials to be mixed in controlled percentages as long as the resultant laboratory prepared mortar meets prescribed compressive strength, water retention, and air content requirements. Mortar types M, S, and N are permitted for construction of reinforced concrete masonry lintels. Although, Type N mortar is prohibited in seismically active areas.

Grout. Ingredients for grout used in masonry construction include cementitious materials and aggre-
gates either course or fine. ASTM C 476 contains requirements for proportions for each of these ingredients. However, it is typical practice to specify compressive strength based on design requirements rather than specifying proportions of each ingredient. The minimum compressive strength of grout in accordance with ASTM C 476 is 2,000 psi or $f_{m}^{\prime}$ whichever is greater.

Reinforcement. Deformed steel bars must comply with the applicable ASTM standards listed in Table 2.1. Grade 60 reinforcement is commonly used although Grades 40 and 50 are permitted.

## DESIGN LOADS

For all designs, the designer must determine the anticipated loads, and the manner in which they act upon the lintel based upon the analysis of the structure under consideration. Vertical loads carried by lintels typically include: (1) distributed loads from the dead weight of the lintel and the masonry above the lintel, and any floor and roof dead and live loads supported by the masonry, and (2) concentrated loads from floor beams, roof joists, and other beams framing into the wall.

Typical loads acting upon a lintel can be separated into four types illustrated in Figure 3-1: (1) uniform load acting over the effective span, (2) a tri-

Figure 3-1: Typical Load Components
angular load, with apex at mid-span, acting over the effective span, (3) concentrated loads, and (4) uniform load acting over a portion of the effective span. The principle of superposition will allow the designer to calculate the effects of these individually and then combine them to determine the overall effect.

### 3.1 Determination of Loads

Lintels are required to carry gravity loads. Gravity loads are generally of two types: dead and live. Dead loads are generally permanent in nature, and can be divided into structure self-weight and superimposed loads. Superimposed loads may include the weight of the walls, floors, roofs, ceilings, partitions, and other similarly incorporated architectural and structural items.

Live loads are produced by the use and occupancy of the building and represent the assumed weight of building occupants, furnishings, equipment, etc. that are distributed to lintels by floor joists that bear on the wall above. Additionally, loads are produced by snow and rain that act on the lintel through the roof trusses or joists. Minimum live loads are mandated by the governing building code or by the American Society of Civil Engineers' Minimum Design Loads for Buildings and Other Structures [4] (ASCE-7). ASCE-7 contains minimum live loads for other loads such as different occupancies and procedures to calculate snow and rain loads.

### 3.2 Load Combinations

Building codes require design loads to be applied on structural members in various combinations. These load combinations are intended to ac-
count for the combined affects of several loadings occurring simultaneously. Accordingly, load combinations, such as dead plus live loads, must be considered since these loadings will most likely occur at the same time. Common load combinations for lintels are presented in Table 3.1. These are based on the provisions of ASCE-7 and are shown for both allowable stress design and strength design methods.

### 3.3 Arching Action

In some instances, the masonry will distribute loads so that they do not act on the lintel. This is called arching action of masonry [5] and is based on the amount
of masonry that is around the lintel. Arching action can be assumed if the following criteria are met:

- masonry wall is laid in running bond
- sufficient wall height above the lintel to form a 45 degree triangle
- wall height above the arch height is at least 8 inches
- minimum end bearing is maintained
- there is sufficient masonry on either side of the opening to resist the induced horizontal thrust
- control joints or other discontinuities are not located adjacent to the opening
Figure 3-2 shows the relationships of these distances.

## Table 3.1: Load Combinations

| Allowable Stress Design Load Combinations ${ }^{\mathbf{a}}$ | Strength Design Load Combinations ${ }^{\text {b,c }}$ |
| :--- | :--- |
| 1. $D$ | 1. $1.4 D$ |
| 2. $D+L+\left(L_{r}\right.$ or $S$ or $\left.R\right)$ | 2. $1.2 D+1.6 L+0.5\left(L_{r}\right.$ or $S$ or $\left.R\right)$ |
|  | 3. $1.2 D+0.5 L+1.6\left(L_{r}\right.$ or $S$ or $\left.R\right)$ |
| a. Based on ASCE 7 [4] section 2.4.1 <br> b. Based on ASCE 74$]$ section 2.3.2 <br> c. The load factor on $L$ in combination 3 shall equal 1.0 for garages, areas occupied as places of public assembly, and all <br> areas where the live load is greater than 100 psf. |  |

Figure 3-2: Arching Action

The design loads applied to a lintel depend on whether arching action is present or not. The types of loads for lintel design are shown in the flow chart of Figure 3-3. If arching is present, the self weight of the lintel, the weight of the wall below the arched portion taken as a triangular load, and concentrated loads are considered. Otherwise, the self weight, the weight of the wall above the lintel as a uniform load, roof and floor loads, and concentrated loads are considered.

Self Weight. Self weight is a uniform load computed based upon the weight of the lintel itself. Usually, the
unit weights of masonry units, concrete, mortar, grout, and reinforcing are combined into a single estimate.

Wall Weight. Because of arching action, only the wall weight within the triangular area below the apex need be considered. The triangular load has a base equal to the effective span length and apex height equal to one -half of the effective span as shown in Figure 3-2. The magnitude will vary as shown in Figure 3-1.

Concentrated Loads. Concentrated loads applied to walls constructed of running bond masonry are as-

## Design Loads

| Yes | Arching action | No |
| :---: | :---: | :---: |
| Loads to consider: <br> - self weight (uniform) <br> - wall weight (triangular) <br> - concentrated loads (partial uniform) |  | Loads to consider: <br> - self weight (uniform) <br> - wall weight (triangular) <br> - concentrated loads (partial uniform) <br> - roof/floor (uniform/concentrated) <br> - concentrated loads (concentrated) |

Figure 3-3: Lintel Design Loads
sumed to be distributed downwards at an angle of thirty degrees from the vertical on each side of bearing, as shown in Figure 3-4 [5]. This is then resolved onto the lintel as a uniform load with maximum length equal to 4 times the thickness of the wall + width of bearing. The magnitude of the load per unit of length is computed from the concentrated load divided by this length. In most cases, this results in a uniform load acting over a portion of the lintel span.

In some cases, a series of concentrated loads may be considered uniform to resolve onto the lintel. The criteria, based on load spacing is described in Section 3.4 on roof/floor loads. If this criteria is met
and the loads are considered uniform, the loading on the lintel would be neglected if the previously specified conditions for arching action were met. Otherwise, each concentrated load would be resolved by the method above.

### 3.4 No Arching Action

If the criteria described in Section 3.3 are not met, the masonry wall will not act as an arch. The loading conditions on the lintel are presented below.

Self Weight. Self weight must be considered and is computed as described previously.

Figure 3-4: Distribution of Concentrated Load Over Running Bond

Wall Weight. In this case wall loads are assumed to act directly on the lintel. The wall thickness and grout spacing are necessary to estimate the wall weight, usually in terms of wall weight per square foot of wall area. The load on the lintel is computed from this weight multiplied by the height of the wall above the lintel.

Roof/Floor Loads. In some instances, a series of concentrated loads on walls laid in running bond may be considered as uniform loads. Relatively
light loads spaced closely together, such as floor joists and rafters in residential construction, may be considered uniformly distributed as shown in Figure 3-5. Historically, these loads have been considered uniformly distributed if the total height of the masonry between bearing and the top of the lintel is equal to or greater than one-third the center to center spacing of the loads.

Wider spaced loads, that may be encountered in industrial and commercial building, are de-

Figure 3-5: Light Roof/Floor Loads
picted in Figure 3-6. In this case, uniform loading is often assumed whenever the load spacing is less than 4 feet and the wall height above the lintel is greater than half the load spacing.

Loads spaced more than 4 feet apart should generally be considered individual concentrated loads and distributed to the lintel as described in the section on arching action.

Concentrated Loads. Concentrated loads over stack bond masonry are not transferred or distributed across vertical joints. This is shown in Figure 3-7. Loads should not be assumed to be transmitted
across vertical joints even if joint reinforcement is used in the wall construction. Concentrated loads applied to running bond construction are resolved as described in Figure 3-4.

### 3.5 Maximum Loads

The loading on a lintel, as described above, can get quite complicated. For example, a lintel under arching action can carry its self weight (uniform), wall weight (triangular), and partial uniform loads from concentrated loads. In this case, the maximum moment or shear may not be at mid-span and the lintel ends, respectively. Complicated loading cases may

Figure 3-6: Heavy Roof/Floor Loads
arise from lintels not subject to arching action. The support conditions are also a factor. Supports may be either simple or continuous. Continuous supports, while not typical, can often be modeled with fixed end supports.

Lintels are modeled as beams. Appendix A shows a few simple load cases for simple and continuous supported beams. In some of the loading cases listed, the maximum moments and shears are either mid-span or at the ends. Consequently, where
these loading cases act at the same time, the moment or shear is the addition of the individual components. For example, for a simply supported lintel under uniform and triangular loads, the maximum moment and shear are :

Maximummoment

$$
w l^{2} / 8+w l^{2} / 12
$$

Maximum shear

$$
w l / 2+w l / 4
$$

Figure 3-7: Distribution of Concentrated Load Over Stack Bond

## LINTEL DESIGN

This section presents the design methods and parameters governing lintels. The allowable stress design method is presented first, followed by the strength design method. Concrete masonry lintels can be designed by either allowable stress (Section 4.1) or strength design (Section 4.2). Precast concrete lintels are designed by strength design methods (Section 4.2.2). Section 4.3, on design parameters, lists the material properties and design assumptions that are used to compute the expected or design lintel strength, for allowable stress and strength design, respectively.

### 4.1 Allowable Stress Design of Concrete Masonry Lintels

The allowable stress design method compares design stresses produced in a member by the applied loads to allowable stresses. The allowable stresses are prescribed by the applicable building code, and are determined by reducing the expected strengths by appropriate factors of safety. The allowable stress values from the MSJC Code are presented in the section 4.4, Design Parameters.

Flexural compressive and tensile stresses in lintels are determined in accordance with accepted allowable stress design principles. The masonry is assumed to resist the compressive forces. Conversely tensile strength of masonry units, concrete, mortar, and grout is neglected and all tensile stresses are assumed to be carried by the reinforcing steel. Flexural members are proportioned such that the maximum tensile and compressive stresses are within the allowable stress limits discussed above.

Flexural members are also designed to resist shear. The member is proportioned such that the
maximum applied shear stress is less than or equal to the allowable shear strength of the masonry or, alternatively shear reinforcement can be provided increase shear strength. When required, shear reinforcement is provided parallel to the direction of the shear force and distributed over a distance based on the effective depth of the member.

The equations governing allowable stress design are listed below:

$$
\begin{aligned}
& n=E_{s} / E_{m} \\
& \rho=\frac{A_{s}}{b d} \\
& k=\sqrt{2 n \rho+(n \rho)^{2}}-n \rho \\
& j=1-(\mathrm{k} / 3) \\
& M_{m}=1 / 2 F_{b} b d^{2} j k \\
& M_{s}=A_{s} F_{s} j d \\
& M_{r}=\text { the lesser of } M_{m} \text { and } M_{s} \\
& V_{m}=F_{v} b d \\
& V_{s}=\frac{A_{v} F_{s} d}{s} \\
& V_{r}=\text { the lesser of } V_{m} \text { and } V_{s}
\end{aligned}
$$

### 4.2 Strength Design

### 4.2.1 Concrete Masonry Lintels

The strength design method compares factored loads to design strengths of the member. It allows the load that produces failure to be predicted and it allows the failure mode to be controlled so that ductile failure
can occur. Based on acceptable strength design principles, the nominal strength of the member is determined and then reduced by strength reduction factors, called phi $(\phi)$ factors. These factors account for any variability in materials and construction practices. The resulting reduced capacity called the design strength of the member, is then compared to the factored loads (see Table 2.1) to ensure the member has adequate capacity.

Flexural compression, tension, and shear are determined in accordance with accepted strength design principles. The tensile strength of masonry is neglected and the nominal strengths are computed.

For fully grouted masonry elements, the nominal flexural strength, $M_{n}$, is calculated as follows:

$$
\begin{gathered}
M_{n}=\left(A_{s} f_{y}\right)\left(d-\frac{a}{2}\right) \\
a=\frac{A_{s} f_{y}}{0.80 f_{m}^{\prime} b}
\end{gathered}
$$

To provide for a prescribed level of ductility in the event of failure, the amount of reinforcement permitted in reinforced masonry construction is limited. The maximum reinforcement ratio, $\rho_{\text {max }}$, is limited in accordance with the equation below. When the actual reinforcement ratio exceeds this maximum, the cross section must be increased to accommodate the selected reinforcement bar or bars.

$$
\rho_{\max }=\frac{0.64 f_{m}^{\prime}\left(\frac{\varepsilon_{m u}}{\varepsilon_{m u}+\alpha \varepsilon_{y}}\right)}{1.25 f_{y}}
$$

Where the tension reinforcement yield strain factor, $\alpha$, is as follows:
$\alpha=5.0$ for walls subjected to in-plane forces, for columns and for beams designed using an $R$ value greater than 1.5.

Shear acting on reinforced masonry members is resisted by the masonry and shear reinforcement, if provided, in accordance with the following:

$$
V_{n}=V_{m}+V_{s}
$$

The nominal shear strength provided by the masonry, $V_{m}$ is determined in accordance with the following:

$$
V_{m}=2.25 A_{n} \sqrt{f_{m}^{\prime}}
$$

When shear reinforcement is incorporated into reinforced masonry construction, the shear strength provided by the reinforcement is calculated in accordance with the following.

$$
V_{S}=0.5\left(A_{V} / s\right) f_{y} d_{v}
$$

### 4.2.2 Precast Concrete Lintels

Nominal flexural strength, $M_{n}$, is calculated per ACI 318 [3]:

$$
\begin{gathered}
M_{n}=A_{s} f_{y}\left(d-\frac{a}{2}\right) \\
a=\frac{A_{s} f_{y}}{0.85 f_{c}^{\prime} b}
\end{gathered}
$$

The amount of reinforcement is also needed to provide for ductility in the event of failure. For precast concrete lintels, the reinforcement, $\rho$, is limited to:

$$
\rho<0.75 \rho_{b}
$$

where:

$$
\rho_{b}=\frac{0.85 f_{c}^{\prime}}{f_{y}} \beta_{1}\left(\frac{87,000}{87,000+f_{y}}\right)
$$

and

$$
\beta_{1}=0.85 \text { for } f_{c}^{\prime} \leq 4,000 \mathrm{psi}
$$

$\beta_{1}=0.85-0.05\left(\frac{f_{c}^{\prime}-4,000}{4,000}\right)$ for $f_{c}^{\prime}>4,000 \mathrm{psi}$
For precast concrete lintels, nominal shear is similar as presented in Section 4.2.1,

$$
V_{n}=V_{c}+V_{s}
$$

The normal shear strength provided by the concrete, $V$, is determined in accordance to:

$$
V_{c}=2 A_{v} \sqrt{f_{c}^{\prime}}
$$

Where shear reinforcement is incorporated, $V_{s}$, is determined by:

$$
V_{s}=\frac{A_{v} f_{y} d}{s}
$$

### 4.3 Design Parameters

Compressive strength of concrete. The requirements for compressive strength of concrete, designated $f_{c}^{\prime}$, are found in Chapter 5 of ACI 318. Unless otherwise specified, $f_{c}^{\prime}$, is the specified compressive strength of concrete based on 28 day strengths.

Compressive strength of masonry. The requirements for complying with the specified compressive strength of masonry, designated $f_{m}^{\prime}$, are found in the MSJC Specification. Either of two methods are used to verify compliance with $f_{m}^{\prime}$ : the unit strength method or the prism test method.

Allowable stresses. The allowable flexural stress for lintels, $F_{b}$ is equal to one-third of $f_{m}^{\prime}$ (MSJC-2.3.3). Allowable shear stress for lintels is equal to the square root of $f_{m}^{\prime}$ (MSJC-2.3.5). The allowable tensile stress for grade 60 reinforcing steel is $24,000 \mathrm{psi}$ (MSJC2.3.2). To summarize, the allowable stresses are:

$$
F_{b}=1 / 3 f_{m}^{\prime}
$$

$$
\begin{gathered}
F_{v}=\sqrt{f_{m}^{\prime}} \\
F_{s}=24,000 \mathrm{psi}
\end{gathered}
$$

Modulus of Elasticity. The modulus of elasticity for concrete masonry is taken as, $E_{m}=900 f_{m}^{\prime}$. For steel, the modulus of elasticity is taken as $29,000,000$ psi (MSJC-1.8). The modulus of elasticity of concrete used is $57,000 \sqrt{f_{c}^{\prime}}$ per ACI 318, Section 8.51.

Strength reduction factors. Reinforced concrete masonry strength reduction factors for flexure and shear are based on Section 3.1.4 of the MSJC Code. For flexure $\phi=0.9$; for shear $\phi=0.8$. Precast concrete strength reduction factors are based on Section 9-3 of ACI 318. For flexure $\phi=0.9$; for shear $\phi=0.75$.

Effective span. The effective span length of a lintel should be the clear span plus the depth of the member, but not be greater than the distance between the support centers (MSJC-2.3.3.4.1). Furthermore, the end bearing should not be less than 4 inches (MSJC2.3.3.4.3). Figure $\mathbf{4} \mathbf{- 1}$ shows the relationship of effective span, end bearing, and clear span.

Figure 4-1: Effective Span Length

Exposed to earth or weather: 2 in . minimum for bars larger than \#5
$1 \frac{1}{2} \mathrm{in}$. minimum for bars \#5 and smaller
Not exposed:
$1 \frac{1}{2} \mathrm{in}$. minimum

Figure 4-2: Detailing Limitations of Reinforcing Bars

Effective width and depth. The effective compressive width, $b$, of a lintel is taken as: the nominal width minus $3 / 8$ inch. The effective depth, $d$, to the tension reinforcement is taken as: nominal depth minus $3 / 8$ inch minus cover depth minus half the diameter of the reinforcing bar.

## Limitations on detailing reinforcing bars within lintels.

 Reinforcing bar size, placement, and protection are limited by the requirements contained in Section 1.12 of the MSJC for masonry and Chapter 7 of ACI 318 for concrete, respectively. Figure 4-2 summarizes these requirements.Lateral support. As an integral part of the wall, lintels are typically considered laterally supported. Lateral support of the compression face of masonry beams is required along the length of the beam at a maximum spacing of 32 times the thickness of the beam (MSJC-2.3.3.4.4).

Embedment of flexural reinforcement. For a concrete masonry lintel to perform properly under service loads, stress transfer between steel and masonry
must occur. The MSJC Code requires that the reinforcing steel be fully developed. This ensures that the mode of failure (if unanticipated overload occurs) would be ductile yielding rather than a non-ductile pullout.

Deflection. Lintel deflection is limited to the effective span length divided by 600 or 0.3 inches (MSJC1.10.1) when used to support unreinforced masonry. This requirement limits excessive deflection which may damage the supported masonry.

Weight Tables. Table 4.1 gives estimates of lintel weights per foot of length for lintels of $4,6,8,10$, and 12 inch thicknesses. The values are for three depths, 8,16 , and 24 inches, and for both lightweight and normal weight concrete masonry units. Precast concrete lintels are assumed to weigh 150 pcf. Tables 4.2, 4.3, 4.4, and 4.5 list wall weights for four wall thickness and various grout spacings.

Typical Details. Figures 4-3, 4-4 and 4-5 show typical lintel construction for simple and continuous support conditions, respectively.

Table 4.1: Lintel Weights

| Lintel Weights in Pounds per Lineal Foot |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Lintel Height (inches-nominal) | Wall Thickness (inches-nominal) |  |  |  |

Figure 4-4: Concrete Masonry Lintel Assembly

Figure 4-5: Precast Concrete Lintel Assembly

## DESIGN EXAMPLES

## EXAMPLE 1

The 18 foot tall wall shown in Figure 5-1 contains an opening that measures 64 inches in length and 48 inches in height. The bottom of the opening is located 40 inches from the base of the wall. The overall length of the wall is sufficient to resist any horizontal thrust induced due to arching action. The specified compressive strength of the assembly is $1,500 \mathrm{psi}$.

The wall is constructed of 12 inch normal weight concrete masonry units laid in running bond. The lintel is to have 8 inches of bearing on each side of the opening and is assumed to be simply supported at each end.

Figure 5-1: Masonry Wall Configuration

Joists are framed into the top of the wall. The distance between joists is 16 inches. Each joist applies a load of 250 pounds dead load and 500 pounds live load.

Check for arching action. Prior to calculating the loads applied to the lintel, the height of masonry required for arching action is determined. The effective span of the lintel is taken as the clear span of the opening plus the depth of the beam - not to exceed the center-to-center distance between supports. Since the depth of the lintel is not known, it can be conservatively assumed that the effective span is the center-to-center distance between supports.

$$
\begin{aligned}
l & =\text { clear span }+ \text { one-half bearing length }+ \text { one-half bearing length } \\
& =64 \text { in. }+(8 / 2) \text { in. }+(8 / 2) \text { in. }=72 \text { inches }
\end{aligned}
$$

## Lintel Design Manual

The height of masonry above the opening is:

$$
\begin{aligned}
H & =(18 \mathrm{ft})(12 \mathrm{in} . / \mathrm{ft})-40 \mathrm{in} .-48 \text { inches } \\
& =128 \text { inches }
\end{aligned}
$$

The height of masonry required above the lintel for arching action to occur is (refer to Figure 3-2):

$$
\begin{aligned}
h & =(\text { effective span } / 2)+8 \text { inches } \\
& =(72 / 2) \text { inches }+8 \text { inches }=44 \text { inches }
\end{aligned}
$$

Therefore, as long as the height of the lintel does not exceed 128 inches -44 inches $=84$ inches arching action may be assumed for this condition.

With arching action, the uniformly applied superimposed loads from the joists are neglected in the design of the lintel.

Concrete masonry lintel - allowable stress design. Assuming arching action will occur, the loads to be considered in this design consist of the self weight of the lintel and the dead load of the wall under the arched portion taken as a triangular load. Further, since arching is assumed, the size (depth) of the lintel will likely be relatively small. Therefore, attempt a design using a 12 in . by 8 in . (width by height) nominal lintel.

From Table 4.1, the self weight of a 12 in . by 8 in . lintel constructed with normal weight units is:

$$
D_{\text {lintel }}=90 \mathrm{lb} / \mathrm{ft}
$$

From Table 4.5, the dead load of a 12 in . face shell bedded 125 pcf wall is:

$$
\text { Wall self weight }=50 \mathrm{lb} / \mathrm{ft}^{2}
$$

For the wall weight, only the triangular portion with height equal to one-half the effective span ( 3 ft ) is considered. The maximum load applied on the lintel from the wall at the apex of the triangle is:

$$
D_{\text {wall }}=\left(50 \mathrm{lb} / \mathrm{ft}^{2}\right)(3 \mathrm{ft})=150 \mathrm{lb} / \mathrm{ft}
$$

Maximum moment and shear forces are computed using the beam diagrams in Appendix A. The maximum moment and shear due to the self weight of the lintel is determined using Figure A-3 as follows:

$$
\begin{aligned}
& M_{\text {lintel }}=w l^{2} / 8=\left(D_{\text {lintel }}\right)\left(l^{2}\right) / 8=(90 \mathrm{lb} / \mathrm{ft})(72 / 12 \mathrm{ft})^{2} / 8=405 \mathrm{ft}-\mathrm{lb} \\
& V_{\text {lintel }}=w l / 2=\left(D_{\text {lintel }}\right)\left(l^{2}\right) / 2=(90 \mathrm{lb} / \mathrm{ft})(72 / 12 \mathrm{ft}) / 2=270 \mathrm{lb}
\end{aligned}
$$

The maximum moment and shear due to the wall weight is determined using Figure A-5 as follows:

$$
\begin{aligned}
& M_{\text {wall }}=w l^{2} / 12=\left(D_{\text {wall }}\right)\left(l^{2}\right) / 12=(150 \mathrm{lb} / \mathrm{ft})(72 / 12 \mathrm{ft})^{2} / 12=450 \mathrm{ft}-\mathrm{lb} \\
& V_{\text {wall }}=w l / 4=\left(D_{\text {wall }}\right)\left(l^{2}\right) / 4=(150 \mathrm{lb} / \mathrm{ft})(72 / 12 \mathrm{ft}) / 4=225 \mathrm{lb}
\end{aligned}
$$

Since the loading from the self weight of the lintel and wall are both symmetrically applied to the lintel, the maximum moment and maximum shear will occur at the same location along the length of the beam and therefore can be added together to obtain the design moment and shear:

$$
\begin{aligned}
& M_{\max }(\text { at the center of the lintel })=M_{\text {lintel }}+M_{\text {wall }}=405 \mathrm{ft}-\mathrm{lb}+450 \mathrm{ft}-\mathrm{lb}=855 \mathrm{ft}-\mathrm{lb} \\
&=10,260 \mathrm{in}-\mathrm{lb} \\
& V_{\max }(\text { at the support of the lintel })=V_{\text {lintel }}+V_{\text {wall }}=270 \mathrm{lb}+225 \mathrm{lb}=495 \mathrm{lb}
\end{aligned}
$$

From Table 6.10, a 12 by 8 inch lintel with one No. 4 bar having a bottom cover of up to 3 inches has sufficient strength to carry the applied design loads.

$$
\begin{aligned}
& M_{\text {provided }}=16560 \mathrm{in}-\mathrm{lb} \\
& V_{\text {provided }}=1969 \mathrm{lb}
\end{aligned}
$$

Check lintel deflection. Because this lintel is supporting unreinforced masonry, the code requires that the deflection of the lintel be limited to $l / 600$ or 0.3 in., whichever is less.

$$
\begin{aligned}
& E=(900)(1,500)=1,350,000 \mathrm{psi} \\
& I=(1 / 12)(11.625 \mathrm{in} .)(7.625 \mathrm{in} .)^{3}=429.5 \mathrm{in} .^{4}
\end{aligned}
$$

From Figure A-3, the maximum deflection due to the lintel self weight is:

$$
\text { Delta }_{\text {lintel }}=5 w l^{4} /[384 \mathrm{EI}]=(5)(90 / 12)(72)^{4} /[(384)(1,350,000)(429.5)]=0.00453 \mathrm{in} .
$$

From Figure A-5, the maximum deflection due to the wall self weight is:

$$
\text { Delta }_{\text {wall }}=w l^{4} /[240 \mathrm{EI}]=(150 / 12)(72)^{4} /[(240)(1,350,000)(429.5)]=0.00241 \mathrm{in} .
$$

Again, since the loading from the self weight of the lintel and wall are both symmetrically applied to the lintel, the deflection from each load will occur at the same location (at the center of the beam) and therefore can be added together to obtain the maximum deflection:

$$
\text { Delta }_{\max }=0.00453 \mathrm{in} .+0.00241 \mathrm{in} .=0.00694 \mathrm{in} .
$$

Since $l / 600=72 / 600=0.12 \mathrm{in}$., not to exceed 0.3 in . this lintel design is sufficient.

Note: Deflections based on cracked sections can be greater and are more difficult to calculate. The deflection calculation above is based on uncracked moment of inertia, $I$. To determine deflection of crack sections see various testbooks such as [5].

## EXAMPLE 2

An interior partition has a 20 foot opening in an 8 inch hollow masonry wall laid in running bond. The lintel will carry only its self-weight and the weight of the wall. The design of the lintel is governed by strength design. The wall configuration is shown in Figure 5-2.

Figure 5-2: Interior Partition

Check for arching action. Prior to calculating the loads applied to the lintel, the height of masonry required for arching action is determined. The effective span of the lintel is taken as the clear span of the opening plus the depth of the beam - not to exceed the center-to-center distance between supports. Since the depth of the lintel is not known, it can be conservatively assumed that the effective span is the center-to-center distance between supports.

$$
\begin{aligned}
l & =\text { clear span }+ \text { one-half bearing length }+ \text { one-half bearing length } \\
& =240 \text { in. }+(8 / 2) \text { in. }+(8 / 2) \text { in. }=248 \text { inches }
\end{aligned}
$$

The height of masonry above the opening is:

$$
\begin{aligned}
H & =(8 \mathrm{ft})(12 \mathrm{in} . \mathrm{ft}) \\
& =96 \text { inches }
\end{aligned}
$$

The height of masonry required above the lintel for arching action to occur is (refer to Figure 3-2):

$$
\begin{aligned}
h & =(\text { effective span } / 2)+8 \text { inches } \\
& =(248 / 2) \text { inches }+8 \text { inches }=132 \text { inches }
\end{aligned}
$$

Given that the actual height above the lintel is less than $h$, arching action is not present. Consequently, the wall load is considered a uniform load as opposed to a triangular load.

Concrete masonry lintel - strength design. The partition carries only the lintel self-weight and the wall above. These dead loads are increased by a factor 1.4 as required by strength design (see Table 3.1). Therefore, the loads are,

$$
\begin{aligned}
& D_{\text {lintel }}=1.4(176)=247 \mathrm{lb} / \mathrm{ft} \text { (assuming a } 24 \mathrm{in} \text {. lintel—Table 4.1) } \\
& D_{\text {wall }}=1.4(36)(8-2)=303 \mathrm{lb} / \mathrm{ft} \text { (assuming } 125 \mathrm{pcf} 8 \text { in. block—Table 4.3) }
\end{aligned}
$$

Both loads are uniform over the lintel, so the maximum moment and shear are,

$$
\begin{aligned}
& \begin{aligned}
M_{\max }=(\text { at the center of the lintel }) w l^{2} / 8=(247+303)(20.67)^{2} / 8 & =29,373 \mathrm{ft}-\mathrm{lb} \\
& =352,480 \mathrm{in} . \mathrm{lb}
\end{aligned} \\
& \\
& V_{\max }=w l / 2=(247+303)(20.67) / 2=5,684 \mathrm{lb}
\end{aligned}
$$

Using strength design Table 6.42, a $8 \times 24$ lintel with 1 No. 5 reinforcing bar with bottom cover 2.5 inches or less is adequate to support the design load.

$$
\begin{aligned}
M_{r^{2}} & =354,932 \mathrm{in} .-\mathrm{lb} \\
V_{\text {provided }} & =16,898 \mathrm{lb}
\end{aligned}
$$

Check lintel deflection. Because this lintel may be supporting unreinforced masonry, the code requires that the deflection of the lintel be limited to $l / 600$ or 0.3 in., whichever is less. Further service loads (unfactored loads) are use for deflection checks.

$$
\begin{aligned}
& E=(900)(1,500)=1,350,000 \mathrm{psi} \\
& I=(1 / 12)(7.625 \mathrm{in} .)(23.625 \mathrm{in} .)^{3}=8378.7 \mathrm{in} .4
\end{aligned}
$$

From Figure A-3, the maximum deflection due to the lintel self weight is:

$$
\text { Delta }_{\text {lintel }}=5 w l^{4} / 384 \mathrm{EI}=(5)(176 / 12)(248)^{4} /[(384)(1,350,000)(8378.7)]=0.06387 \mathrm{in} .
$$

From Figure A-3 again, the maximum deflection due to the wall self weight is:

$$
\text { Delta }_{\text {wall }}=5 w l^{4} / 384 \mathrm{EI}=(5)(303 / 12)(248)^{4} /[(384)(1,350,000)(8378.7)]=0.10995 \mathrm{in} .
$$

Again, since the loading from the self weight of the lintel and wall are both symmetrically applied to the lintel, the deflection from each load will occur at the same location (at the center of the beam) and therefore can be added together to obtain the maximum deflection:

$$
\text { Delta }_{\max }=0.06387 \mathrm{in} .+0.10995 \mathrm{in} .=0.17382 \mathrm{in} .
$$

Since $l / 600=248 / 600=0.41 \mathrm{in}$., the deflection limit not to exceed 0.3 in . controls. Since the actual calculated value is less than this, the lintel design is adequate.

## EXAMPLE 3

A residential basement needs a lintel to support an opening for an exit door. The wall supports a floor similar to that shown in Figure 3-5. Figure 5-3 shows the arrangement of the basement wall. It was determined that the floor live load is $400 \mathrm{lbs} / \mathrm{joist}$ and the floor dead load is $100 \mathrm{lbs} / \mathrm{joist}$. A concrete masonry lintel and a precast concrete lintel will be designed. A concrete masonry lintel and a precast concrete lintel will be designed.

Figure 5-3: Residential Basement
Check for arching action. Assuming 8 in . end bearing, $l=4 \mathrm{ft} 8 \mathrm{in}$. and $h=2 \mathrm{ft} 4 \mathrm{in}$. Arching action cannot be assumed, because there is not enough masonry above the door.

Floor loading. First, the floor load spacing is checked. Recall, that if the height of masonry above the lintel is at least $1 / 3$ the center-to center load spacing, the loading is resolved onto the lintel as uniformly distributed. Assuming an 8 inch lintel, the height of masonry above the lintel is,

$$
h_{m}=(8 \mathrm{ft} 0 \mathrm{in} .-6 \mathrm{ft} 8 \mathrm{in} .)-8 \mathrm{in} .=8 \mathrm{in} .
$$

There is sufficient masonry above the lintel so that the floor load is considered uniform. Given that, the uniform load acting on the lintel is,

$$
w={ }^{12} /{ }_{16} P
$$

Design loads. Using the above equation, the design live load is,

$$
w_{L}={ }^{12} / 16(400)=300 \mathrm{lb} / \mathrm{ft}
$$

The dead loads on the lintel include the floor weight, lintel self-weight, and the wall weight. Note that the wall weight is considered uniform instead of triangular because arching action is not present. The dead loads are,

$$
\begin{aligned}
& D_{\text {floor }}=\left(\frac{12}{16}\right)(100)=75 \mathrm{lb} / \mathrm{ft} \\
& D_{\text {lintel }}=59 \mathrm{lb} / \mathrm{ft}(\text { assuming } 8 \mathrm{in} . \text { normal weight units - Table } 4.1) \\
& \left.D_{\text {wall }}=36(8 / 12)=24 \mathrm{lb} / \mathrm{ft} \text { (assuming } 125 \mathrm{pcf} \text { block - Table } 4.3\right)
\end{aligned}
$$

Concrete masonry lintel - allowable stress design. All the loads are uniformly distributed, so the maximum moment and shear are,

$$
\begin{aligned}
M_{\max }=(300+75+59+24)(4.67)^{2} / 8 & =1,249 \mathrm{ft}-\mathrm{lb} \\
& =14,983 \mathrm{in} .-\mathrm{lb} \\
V_{\max }=(300+75+59+24)(4.67) / 2 & =1,069 \mathrm{lb}
\end{aligned}
$$

Using Table 6.4, an $8 \times 8$ lintel with 1 No. 4 reinforcing bar and 2.5 inches cover or less has adequate capacity.

$$
\left(V_{\text {all }}=1,439 \mathrm{lb}, M_{\text {all }}=14,997 \mathrm{in} .-\mathrm{lb}\right)
$$

Concrete masonry lintel - strength design. The maximum moment and shear are:

$$
\begin{aligned}
M_{\max }=[1.6(300)+1.2(75+59+24)](4.67)^{2} / 8 & =1,825 \mathrm{ft}-\mathrm{lb} \\
& =21,905 \mathrm{in}-\mathrm{lb} \\
V_{\max }=[1.6(300)+1.2(75+59+24)](4.67)^{2} / 2 & =1,564 \mathrm{lb}
\end{aligned}
$$

From Table 6.29, an $8 \times 16$ in. lintel with 1 No. 4 reinforcing bar and 3 inches cover or less is adequate.

$$
\begin{aligned}
M_{\text {provided }} & =126,568 \mathrm{in}-\mathrm{lb} \\
V_{\text {provided }} & =8,305 \mathrm{lb}
\end{aligned}
$$

By inspection the additional weight of a 16 inch lintel vs. the 8 inch lintel assumed will not exceed provided capacity.

Precast concrete lintel design. $M_{\max }$ and $V_{\max }$ are essentially the same as calculated for masonry strength design above (except for a slight increase in the dead load of the lintel due to a higher density of the concrete which by inspection will not exceed provided capacity).

From Table 6.51 and assuming the strength of concrete equal to 3000 psi , a 8 by 8 inch precast concrete lintel with one No. 4 bar having a bottom cover of up to 3 inches has sufficient strength to carry the applied design loads.

$$
\begin{aligned}
M_{\text {provided }} & =60,117 \mathrm{in}-\mathrm{lb} \\
V_{\text {provided }} & =4,171 \mathrm{lb}
\end{aligned}
$$

Note: If this lintel is supporting unreinforced masonry a deflection check should be made for all three designs similar to Examples 1 and 2.

## EXAMPLE 4

An industrial warehouse has a garage door that spans 12 feet. The one story warehouse supports a roof and the loading on the wall was determined to be $4,500 \mathrm{lb}$ concentrated loads at 5 ft o.c. ( 3,000 live load and 1,500 dead load). Strength design will be used and Figure 5-4 shows the wall configuration. The wall is constructed of 12 in . concrete masonry laid in stack bond with No. 6 reinforcing bars spaced 48 inches oncenter. Recall that with stack bond, masonry arching action is not present. Additionally, with stack bond masonry the roof loads are concentrated loads acting on the lintel (see Figure 3-7). Design a concrete masonry lintel using strength design.

Figure 5-4: Warehouse Wall
Design loads. The lintel will be loaded with a combination of uniform and concentrated loads as shown in Figure 5-5. The lintel is assumed 24 inches high and carries 2 feet of wall above. The loads shown in the figure are increased by load factors from Table 3-1: 1.2 for dead loads and 1.6 for live loads.

Since the loads are symmetrical, the maximum moment will be at the center of the span and will be the sum of the individual moments at that point.

Concrete masonry lintel - strength deisgn.
Moments:
Left $P$ (Figure A-2)

$$
\mathrm{M}=6,600(1.33)[1-(6.33 / 12.67)]=4,389 \mathrm{ft}-\mathrm{lb}
$$

Middle $P$ (Figure A-1)

$$
\mathrm{M}=6,600(12.67) / 4 \quad=20,906 \mathrm{ft}-\mathrm{lb}
$$

$$
P=1 \cdot 2(1,500)+1.6(3,000)=6,600 \mathrm{lb}
$$

## Figure 5-5: Lintel Loading

Right $P$ (same as left $P$ by symmetry) $\quad=4,389 \mathrm{ft}-\mathrm{lb}$
Uniform load (Figure A-3)

$$
\begin{array}{rlrl}
\mathrm{M}=(151+322)(12.67)^{2} / 8 & & 9,491 \mathrm{ft}-\mathrm{lb} \\
& M_{\max } & = & 39,175 \\
\mathrm{ft}-\mathrm{lb} \\
& = & 470,100 & \mathrm{in} . \mathrm{lb}
\end{array}
$$

Shear:
By inspection, the loads are symmetrical. Maximum shear is at each support and equal to $1 / 2$ total vertical load. (Alternatively, the shear per each load could be determined at each support and then summed similar to the moment calculation.)
$V_{\text {max }}=[3(6,600)+12.67(151+322)] / 2=12,896 \mathrm{lb}$
Table 6.36 shows that a $12 \times 24$ lintel with 1 No. 6 bar will support the load as long as a 2 inch cover depth is maintained.

$$
\begin{aligned}
M_{\text {provided }} & =479,530 \mathrm{in}-\mathrm{lb} \\
V_{\text {provided }} & =24,717 \mathrm{lb}
\end{aligned}
$$

Deflection check. A deflection check is not necessary here since the masonry being supported is reinforced unless serviceability requirements dictate otherwise.

## LINTEL DESIGN TABLES

The design tables contained herein list the allowable - for allowable stress design-and de-sign-for strength design - shear and moments for reinforced concrete masonry lintels. Table 6.1 to Table 6.24 are based on allowable stress design, while Table 6.25 to Table 6.48 are based on strength design. The tables are by lintel width and height and list shear and moment for a certain reinforcing bar size and specified cover depth. The nominal lintel widths and heights are: $6,8,10,12$ inches and $8,16,24$ inches, respectively.

Following the masonry lintel tables, design tables for reinforced concrete lintels are presented. These tables, 6.49 to 6.52, list design shear and moment strengths using the strength design provisions of ACI 318 [3]. The tables include values for $4 \times 8$ in., $6 \times 8$ in., and $8 \times 8$ in. and $8 \times 16$ in. nominal lintels and 3 concrete compressive strengths.

$f_{m}^{\prime}=1,500 \mathrm{psi}$
Bottom
Cover
a. Tables based strength design.
b. Moment and shear capacity based on $f_{m}^{\prime}=1,500 \mathrm{psi}$ and grade 60 reinforcement, strength reduction factors taken as $\phi=0.9$ for moment and $\phi=0.8$ for shear.
c. Not permitted for masonry exposed to earth or weather (Figure 4-2).
d. Shading indicates lintel section exceeds maximum reinforcement ratio in Section 4.2.2.

a. Tables based strength design.
b. Moment and shear capacity based on $f_{m}^{\prime}=1,500 \mathrm{psi}$ and grade 60 reinforcement, strength reduction factors taken as $\phi=0.9$ for moment and $\phi=0.8$ for shear.
c. Not permitted for masonry exposed to earth or weather (Figure 4-2).
d. Shading indicates lintel section exceeds maximum reinforcement ratio in Section 4.2.2.
